# Decision Trees in Statistics

# Trees

---

- In many situations, decisions are made by hierarchical rules. (Is your team going to playoff?)
- Which variable is most important?
  - ✓ Decision trees can give good hints
- Categorical dependent variable: Classification tree
- Quantitative dependent variable: Regression tree
- Predictors: can mix categorical & quantitative
- Trees can be tuned and pruned.
- *Random Forests* – with many many trees, averaged, tuned, randomized (cross-validation etc)

# Regression Tree Example

---

- Predict baseball player salary
  - ❖ Example by Rebecca C. Steorts, Duke University
- Use **binary recursive splitting**
- The predictor solution space is divided into regions
- Branches are created by **cutpoints** that divide the space into regions
- Each region is defined by its average values of the variables (indep and/or dep), c.f. K-means
- Cutpoints are determined by minimizing MSE of both new regions.
- Cuts continue recursively

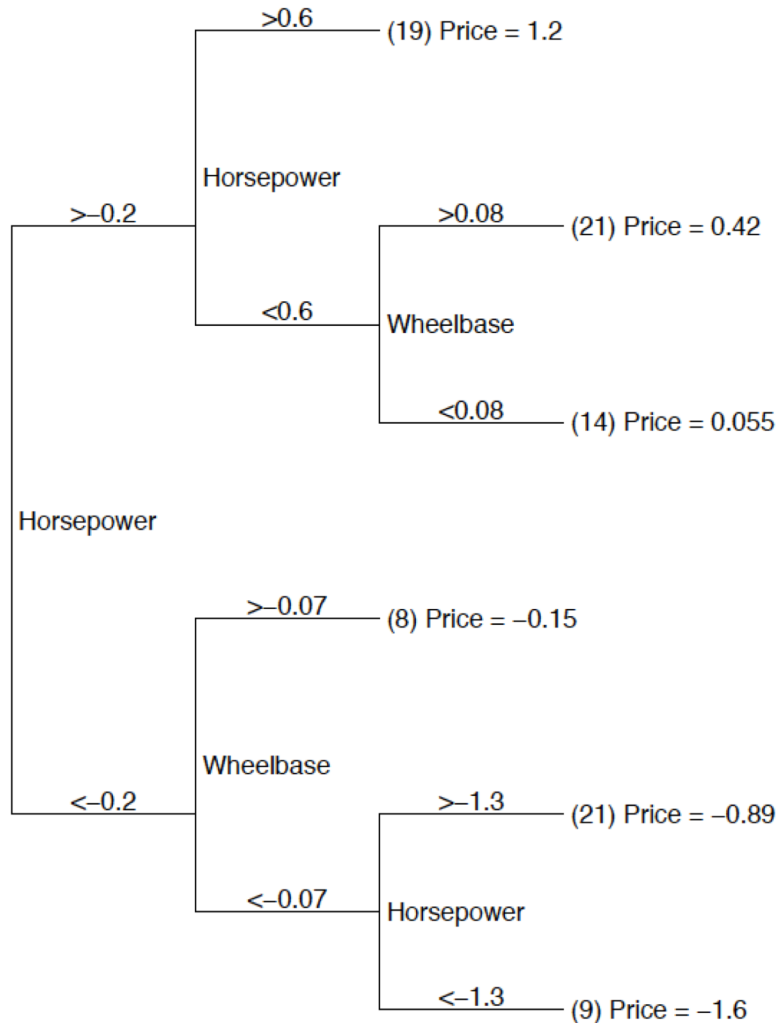

# Regression Tree Example

## Recursive Binary Splitting

# Regression Tree Example

Predicting price of 1993-model cars.

All variables standardized.

Note the order of variables examined depends previous questions.

The numbers in parentheses at the leaves indicate how many cases (data points) belong to each leaf.

Source: CMU Data Mining lectures  
<http://www.stat.cmu.edu/~cshalizi/350-2006/lecture-10.pdf>

Figure 1: Regression tree for predicting price of 1993-model cars. All features have been standardized to have zero mean and unit variance. Note that the order in which variables are examined depends on the answers to previous questions. The numbers in parentheses at the leaves indicate how many cases (data points) belong to each leaf.

# Regression Tree Example

Figure 2: The partition of the data implied by the regression tree from Figure 1. Notice that all the dividing lines are parallel to the axes, because each internal node checks whether a single variable is above or below a given value.

Predicting price of 1993-model cars.

Partitions of solution space

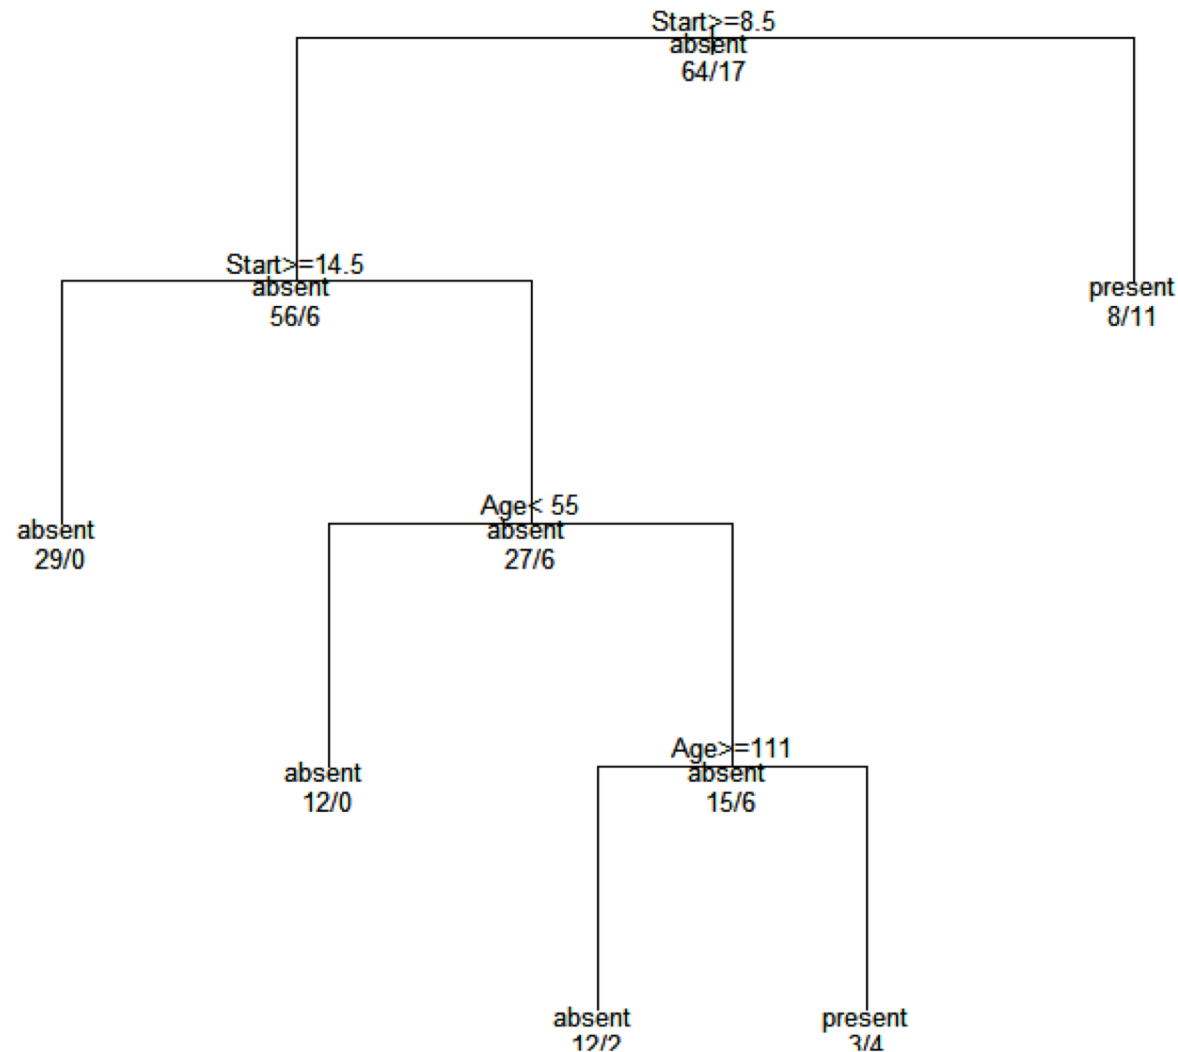

Quantitative response variable represented by color.

# Random Forest

---

- Forest contains many many trees
- Each tree from different sample
- Each split chosen from random sample of possible predictors
- Usually  $m = \sqrt{p}$  possible predictors
- Useful when many independent variables or one strong and many weak predictors
- If predicting within the space of the sample, decision tree might show better accuracy
- When predicting unexpected (untrained) data, random forest usually much better
